VUOOM
Robotic platform system for RST aircrafts and airports
Aris Symeonidis

Presented at: Regional Sky Transit - Sustainable Aviation. April 21, 2017
Abstract

Using electric autonomous flat-top wheeled platform ("platform") - for assisting RST aircrafts for landing, be ferried about and then for taking off - during airport and runway operations enables extremely-short takeoff or landing (ESTOL) capability for long-range electric fixed-wing aircraft between low-noise highly-localized RST skyparks. Tolerable acceleration of .6 g brings aircraft to 45 mph takeoff speed in 35 meters, enabling skyparks to be comparably land intensive to parking lots. For VTOLs, the platforms enable them to be ferried and moved about for increased ground efficiencies and flight cadence, and more relaxed passenger experience.

Fig. 1: DG-1000: contemporary glider, glide ratio 46, wingspan 20 m, 750 kg gr. weight. (Landing-gearless).

Fig. 2: The platform-car will enable maximum delegation from the aircraft to the ground of the aircraft’s power requirements, flight operations and management overhead, cadence and safety.

Part masses of comparable electric-powered aircraft for 2-passenger RST

- 1400 kg aircraft takeoff weight
  - 750 kg base weight
  - 300 kg two occupants
  - 50 kg <260 kW 95% \( \eta \) motor
  - 200 kg Li-ion battery at 140 Wh/kg; 24 kWh, w/ 20 kWh depletion/100km
  - 50 kg more structures, carbon fiber framing, aluminum skin
  - 50 kg more controls/avionics
  - 8000 kg platform car - jacked-up 2x-scale Model-X-platform with robotic/magnetic catch latch
  - 10^4 kg asphalt infrastructure street-integrated gates & skypark

“Regional Sky Transit (RST) is the name applied to a future system of ubiquitous, short-range, on-demand, affordable, point-to-point delivery of people by electrically-powered, autonomous, ultra-quiet Sky Taxis. The RST system will rely upon easily accessible small, “pocket skyparks” adequate for vertical or extremely short take off and landing (V/ESTOL) that allow the public to minimize ground travel time (GTT) on short trips within highly populated mega-regions.” -Dr. Brian Seeley [1]
Summary

Aircraft equipped with a small retractable latch would land on self-driving platform-cars velocity matching the aircraft. The cars would provide deceleration to gate taxiing speed, giving extremely-short landing capability and rapid throughput. The same latch can be used for landing, taxiing restraint, and catapult launch. ESTOL capability in fixed-wing aircraft creates a better option for RST due to higher glide efficiency and range, and lower costs and noise compared to VTOL aircraft options. Vertical takeoff requires a thrust/weight greater than 1, and more power increases noise, a primal concern[2].

The power now available in batteries enables an electromagnet on the platform-car’s latch hook to magnetize a ferromagnetic aircraft latch rod, inducing attractive force, reducing employment of control surfaces on aircraft for aligning & maneuvering latch hook into slot during landing.

Door-to-door transit time costs [1]
- gate to takeoff, 15 seconds achievable
- flight cruising: 120 mph, car avg: -30 mph, train: -30 mph
- landing to gate, 15 s achievable
- street to gate, 20 s achievable, TBD skypark design
- skypark to final destinations, target: <6 min, TBD skypark proximity

Energy use - $0.10/kWh grid cost
- 2017 Tesla Model S: energy consumption 32 kWh/100 mi = 20 kWh/100km
- 20:1 L/D 1400 kg Aircraft 70 kgf * 100 km = 7.0e7 Nm = 20 kWh/100km
  - both have room for future improvement from higher battery energy densities and lower gross weights
  - Range ∝ Aerodynamics, battery density, gross weight

Features
- Safety - redundant parallel power, battery, control systems, 45 mph stall speed, high glide ratio, parachutes, emergency landing/crash-slide/skid airbags in body and cabin
- Convenience - Enter and exit cabin at gates, fast taxi to runway
- Pleasure - panoramic view, low vibration, HUD/laptop/internet productivity
- Noise - target <48 dB continuous noise, distributed electric propulsion
- Piloting - automated in future with simplifying power of electromagnet or robotic hook

Aerodynamics
Range is limited by the aerodynamic performance of aircraft. Lift/Drag ratio is energy efficiency of aircraft’s flying surfaces. Achieving L/D over 20 may require wingspans of 15-20 m and great design. Hinged wings possible for tight skypark space.
Purported stable fuselage length (m) = .3 * Wingspan + 2.5

No parasitic drag protrusions for landing/taxiing/takeoff gear; small retractable latch

© 2017, Vuoom.com patent pending
eliminates bulky landing gear/wheels often comprising 10% of gross aircraft weight.

**Aircraft Structure**
- Strength/weight materials, carbon fiber composite frame & aluminum skin
- Rapid interchangeable appx. 24 kWh battery packs
- Appx. yield loads = 1.5 (safety factor) * 4.5 g acceleration (by gusts)
- Ferromagnetic material latch rod for high magnetic attraction
- Traditional semimonocoque frame, wing spars, ribs, skin
- Battery near wing box for center of lift near center of mass

**Aircraft Controls**
Extremely short landing prefers descent maneuverability steeper than cruise-flight glide slope. Gimbaling electric fans for thrust vectoring is a flight control possibility. Tradition is set of ailerons, elevators, and rudder on tail stabilizer empennage.

**Aircraft Propulsion**
Noise generation with thrust generation. Additional fans reduce peak noise output at cost of more parts. Siemens makes a 50 kg, sustained 260kW output electric-aircraft-dedicated motor, solving propulsion for electric aircraft eventually beyond 4-6 passengers. Distributed propulsion over several motors & fans may be needed to lower noise.

- 20:1 L/D 1400kg 2-passenger craft in steady, level, unaccelerated flight:
  - 70 kgf/490 N drag matched by thrust
  - 120 mph/193 kph/54 m/s optimal efficiency cruise speed
  - 700 N * 54 m/s = 38 kW constant engine output

-Low-noise, high-efficiency propellers preferred
-Redundant parallel battery, motor, computer, & control architectures

Achieving a steep descent for shorter landing paths may be assisted by reversing thrust direction, an advantage of electric motors.

US Navy aircraft carrier launch catapult & F-35 front hook.
F-18 with tail hook extended, landing.

Electromagnetic-Mechanical Hook + Latch: For Landing, Takeoff, & Taxiing

It will be seen how effectively the self-driving platform-car can be programmed to work together with the control surfaces of the plane to perform highly reliable and safe hook-latch landings.

The latch could be very light, small, and retractable given the low forces involved with small aircraft. Electromagnetic attraction of a ferromagnetic latch could also produce hundreds of pounds of attractive force once the latch is within ~6-12” of the car electromagnet.

.6 g acceleration from 0-45 mph spans 35 meters. In landing, the platform-car must speed match the landing aircraft in its glide, latch and lock it, and provide deceleration to the taxi speed towards the gate for a rapid disembarking, battery swapping, and new passenger docking.

If both the plane’s belly latch and platform-car hook can rotate, a hook used for landing

© 2017, Vuoom.com patent pending
can spin around to face forward, ready to release the aircraft in an accelerated takeoff. By securing the docked aircraft, the aircraft’s latch would be spun while the aircraft remained docked on the platform-car.

The top portion of the hook can be robotically articulated to affirmatively grab the latch at its steady flying position.

**Ground Activities Improvement**

**Airport Taxiing and Aircraft automated ferrying**

The self-driving autonomous platform-cars will control all movements on the ground - from landing, to taxiing, to passenger boarding/disembarking area, to take-off. Efficient, safe, single-command for the on-ground taxiing-decision systems of aircrafts. Especially as there may be more than one service provider and aircraft model with varying aircrafts and software. Benefits include: reduction in power consumption while on the ground as the platform-car will do all movement; increased flight cadence; safety may increase as well; faster passenger movements and relaxed on-boarding and debarking experience (from the passenger-pods); etc. The suspension of the car can smooth impulse of a sudden downward gust shock during landing.

**Conclusion**

A principle is to reduce, delegate and shift all possible hardware (e.g. landing/taking-off) and software-decision-ing functions (e.g. taxiing) from the aircraft to the ground-based systems.

Ever-increasing battery energy densities will compel innovative new aircraft designs. By providing takeoff acceleration with instant-torque wheel motors on a car, the shortest takeoff is made possible, with none of the motor, wheel, or brake mass needing to be retracted into the belly of the aircraft. The significant effect of aircraft gross weight on range demands elimination of all non-essential mass from the flight phase. The system described increases aircraft ranges, increases speed of skypark operations, decreases size requirement of skyparks, and maximally decreases noise caused by aircraft by needing lower power/weight ratio than vertical takeoffs. More aircraft and skypark technologies and systems will be developed to increase the economics and value of Regional Sky Transit.

Addendum 1 - Additional Uses and Designs

Aircraft at Takeoff and Landing

For aircrafts with landing gear and combined use skypports; runway spur to load onto the platform-car

Automated passenger-pod-car --- passengers will leisurely check-in and seat/unseat themselves at the RST sky-lounge, pay the fare at the self-ticketing POS installed and integrated at the pod system, no need to climb in/walk to and from the aircraft/tarmac; improved passenger experience, the disabled; the pod will be moved into/out of the aircraft. Pod design will be minimalistic, e.g. only the seating-pod compartment is loaded.
Compact airport for ESTOL and VSTOL (not to scale)

The platform-car repurposed for --- self-driving/robot baggage/cargo cars
